Cedar tree revetments are a cost-effective, bioengineering practice that can be used to stabilize actively eroding riverbanks. Anoka Conservation District (ACD) staff installed a cedar tree revetment on a residential property that borders the Mississippi River in Ramsey during the fall of 2013. Erosion at the property, which was dominated by bank undercutting, was in the beginning stages of creating a more serious issue. Bare soil and tree roots were becoming clearly visible as a result of the erosion. Installation of the 180 foot revetment will slow or stop the erosion and reduce the likelihood of a much larger and more expensive corrective project in the future. Excessive erosion along riverbanks threatens property and associated structures, contributes sediment and nutrients to the receiving water body, and eliminates wildlife habitat. The cedar tree revetment installed as part of this project works to correct these problems. The project was funded through landowner contributions, The Minnesota Conservation Corp (MCC), and ACD in-kind contributions.

**Project Specs**

- **Date Installed**: November 2013
- **Project Length**: 180 feet

**Project Funding**

- **Landowner**: $1,955.13
- **MCC**: $2,200.00
- **ACD In-Kind**: $1,497.28
- **Total Project Cost**: $5,652.41

**Installation Process**

Pre-stabilization conditions consisted of an actively eroding riverbank and sparse understory vegetation, which provided no benefits to water quality. Bare soil and exposed tree roots were becoming clearly visible.

Cedar trees were tied together using cable and cable clips. The trees were then secured to the riverbank using a duckbill anchor with the trunks facing upstream to divert the flow of water away from the bank.

The cedar trees lie parallel to the shoreline and create an area of decreased turbulence that decreases bank erosion and actually allows sediment deposition to rebuild the riverbank.

Completed project during high water in the spring of 2014.
